

Affest verifies the fact before a portfolio can act.

Affest lets an AI agent help manage a portfolio without giving that agent unlimited control. When something happens on Ethereum, Affest asks Attestcoin for cryptographic proof. Creditcoin checks the proof before any strategy action is allowed.

THE VERIFIED FLOW

01	Ethereum Sepolia A user creates a PortfolioSignal event.
02	Attestcoin The source transaction is included in an attested block and a proof is built.
03	Creditcoin CC3 Affest verifies the proof, receipt, event, user, asset, amount, and signal type.
04	On-chain policy Limits, allocation, expiry, pause, and replay rules are checked.
05	Portfolio action The action is approved by the user or executed within the policy.

WHAT ATTESTCOIN PROVES

Attestcoin proves that the Ethereum transaction is included in an attested source-chain block. It gives Affest evidence that can be checked on Creditcoin.

WHAT AFFEST CHECKS AFTER PROOF

Affest still checks that the receipt succeeded, the event came from the right contract, the event fields match the strategy, and the source event has not been used before.

WHY THIS MATTERS

A worker, database, or AI model can report an observation. None of them can grant permission. The Creditcoin contracts make the final decision.

SIMPLE SECURITY PROMISE

The agent can read, explain, plan, and request. It cannot access private keys, send arbitrary calldata, or bypass the user's limits.

JUDGE TAKEAWAY

An AI portfolio manager can react to a verified event on another blockchain without trusting our backend and without receiving unrestricted access to the user's funds.

Testnet only. Attestcoin verification is real and contract-enforced. The CC3 swap adapter is a labelled demo adapter while a reliable documented CC3 DEX route is unavailable.
